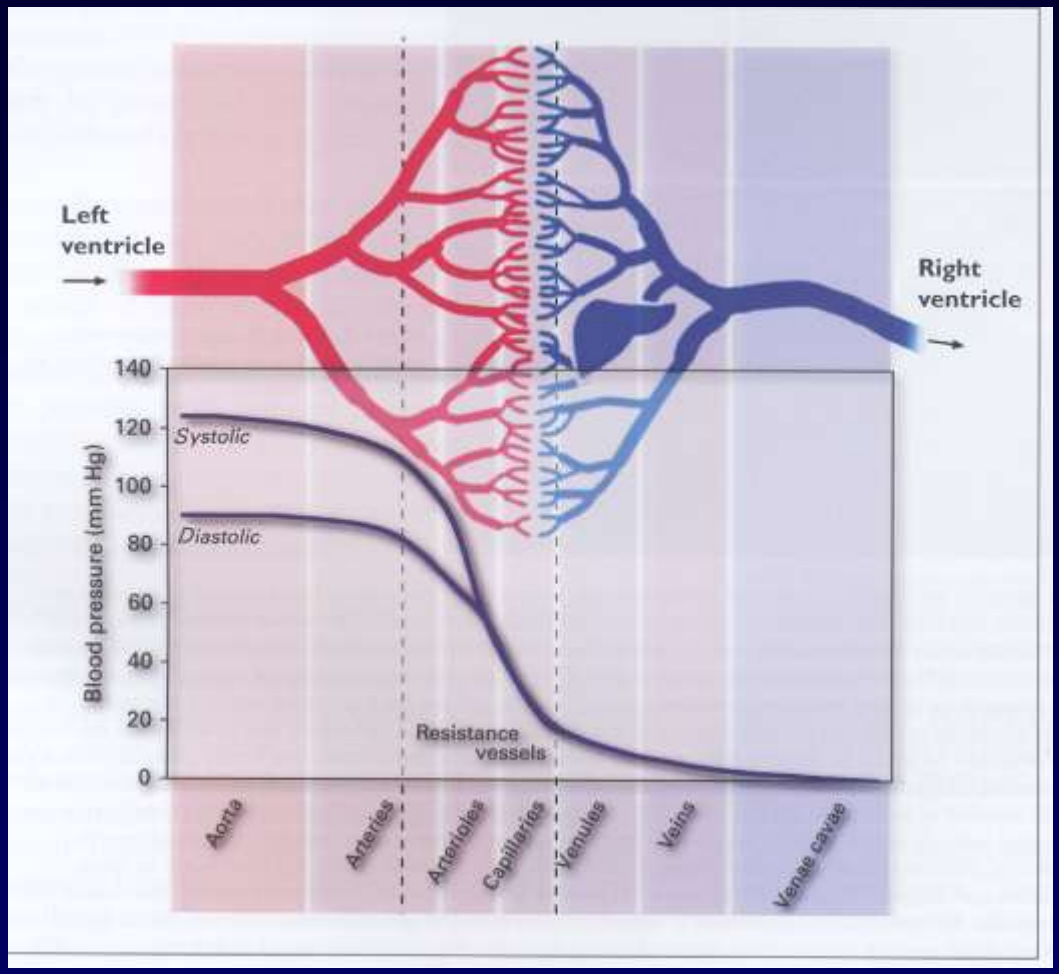
Resistance arteries are key elements in the control of blood pressure



The main drop in hydrostatic pressure occurs al the level of resistance arteries; i.e. the terminal arterioles and the microcirculation. These are vessels with a luminal diameter of less than approximately 400 µm (small arteries/arterioles) and 100 µm (arterioles/capillaries)

Total peripheral resistance in terminal arteries and arterioles amounts to 45% to 50%, in capillaries to 23% to 30%, in venules to 3% to 4%, and to 3% in veins. Thus, structural changes in small arteries and disappearance (rarefaction) of capillaries strongly affect blood pressure.

SMALL RESISTANCE ARTERIES

An increase in the wall-lumen ratio of small arteries can be measured in subcutaneous tissues obtained through gluteal biopsies.

These measurements can demonstrate early alterations in diabetes and hypertension and have a predictive value for CV morbidity and mortality, but the invasiveness of the method makes this approach unsuitable for general use.

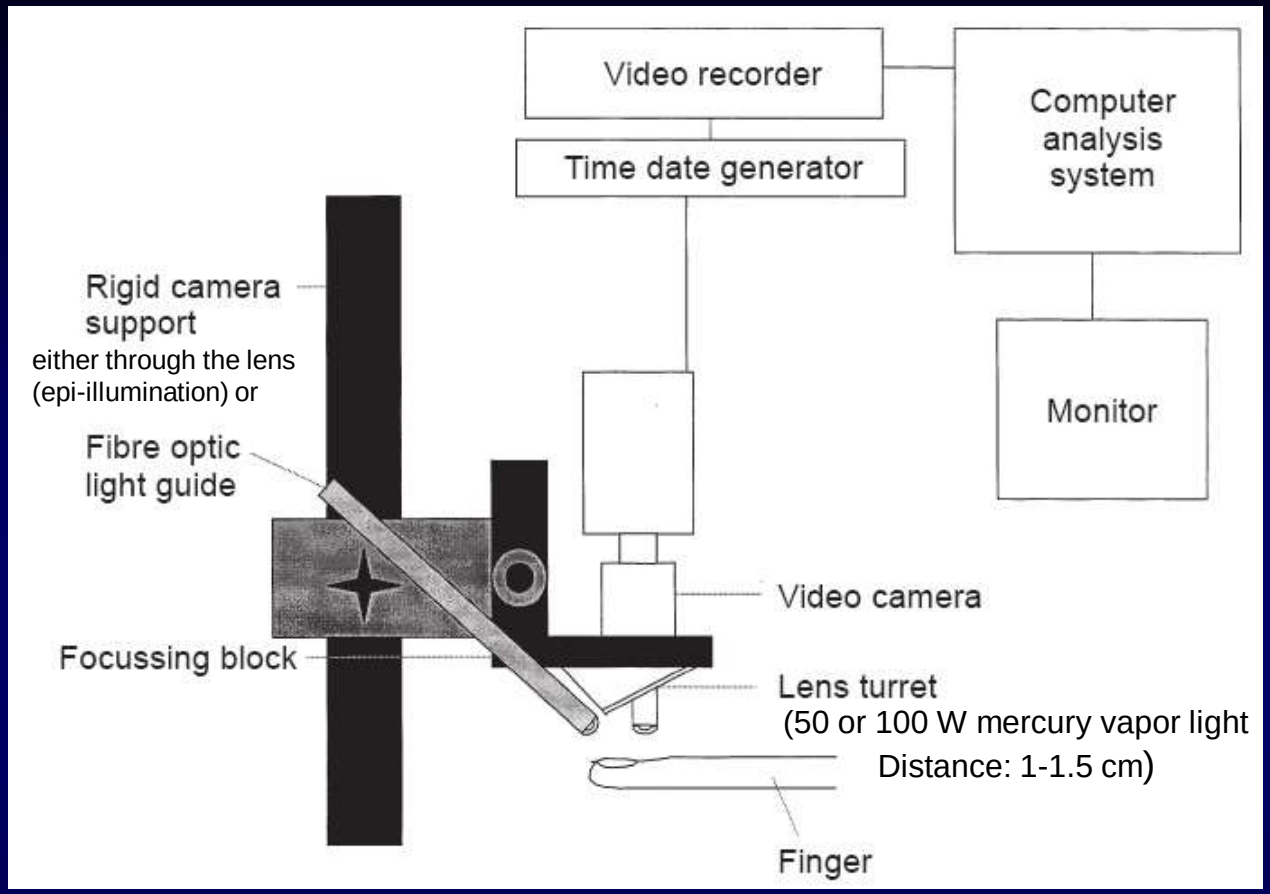
Videomicroscopy - Capillaroscopy (intra-vital capillaroscopy)



Capillaroscopy or intravital videomicroscopy is a technique providing a 2-D projection of a 3-D capillary network. It generates high-contrast images, videotapes or photographs of skin capillaries by means of television, video and/or informatic systems. It allows the assessment of capillary morphology and capillary density (traditional capillaroscopy), capillary flow velocity (dynamic capillaroscopy), capillary red cell column width.

From a structural point of view, the most interesting parameter to be analyzed by capillaroscopy is capillary density. Capillary density is defined as the number of capillaries per unit of skin area. It is measured recording images from the capillary microscope and counting the capillaries in a known skin area. Depending on the underlying investigated area, the capillaries will appear as black dots. (if they are perpendicular to the surface), lines (if the capillaries are lying on an oblique surface) or both. Red blood cells look black in capillaroscopy as the emission spectrum of the mercury lamp is similar to the absorption spectrum of haemoglobin (that is 370-450 nm). Traditional capillaroscopy cannot directly show capillaries that are not perfused at rest. Inducing venous congestion for a few minutes allows the recruitment of previously unperfused vessels, in order to gather information about the total density of vessels of the capillary district, including recruited vessels.

Structural Skin Capillary Rarefaction in Essential Hypertension

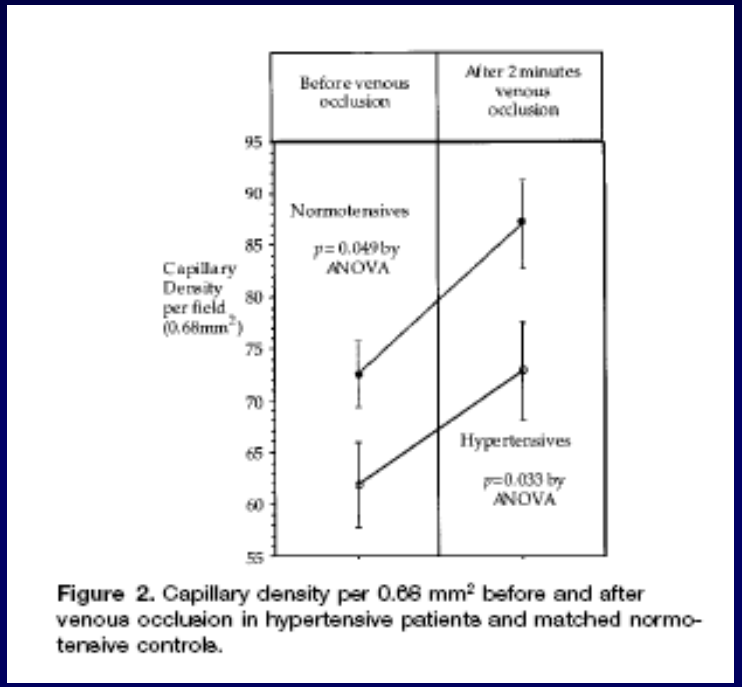

Figure 2. Capillary density per 0.66 mm² before and after venous occlusion in hypertensive patients and matched normotensive controls.

"The aim of this study was to assess the extent of structural versus functional capillary rarefaction in the skin of dorsum of fingers in essential hypertension. The capillary microcirculation was examined with video microscopy before and after maximizing the number of perfused capillaries by venous congestion. The study group comprised 17 patients with essential hypertension (mean supine blood pressure, 155/96 mm Hg) and 17 closely matched normotensive controls (mean blood pressure, 127/77 mm Hg). We used intravital video microscopy with an epi-illuminated microscope to examine the skin of the dorsum of left middle phalanx before and after venous congestion at 60 mm Hg for 2 minutes"

Schematic outline of adaptive optics imaging system. A beam of light enters the eye, and a small amount is reflected back out of the eye and into the optical system. Reflected light is altered by the deformable mirror for optical aberrations based on measurements made by the wave-front sensor. Information about the aberrations of the wave front is processed by the control system that provides feedback to the deformable mirror

Objective: Antiangiogenic therapies (tyrosine kinase inhibitors-TKI and direct anti-VEGF monoclonal antibodies) are being increasingly used in the treatment of solid tumors; hypertension represents a common side effect of these agents. Several mechanisms are involved in the development of hypertension, including microvascular rarefaction and other microvascular alterations. Therefore, the aim of our study was to evaluate whether TKI and direct anti-VEGF agents may affect the structure of retinal arterioles or capillary density.

Design and Methods: We investigated 20 patients with a diagnosis of cancer who underwent a treatment with either a TKI or an anti-VEGF antibody. Patients were submitted to ambulatory monitoring blood pressure for blood pressure evaluation. Basal and total capillary density were assessed by capillaroscopy whereas, retinal arteriole morphology was measured by Adaptive Optics. Patients were evaluated before starting the antiangiogenic therapy (T0) and re-evaluated after 3 (T3) and 6 (T6) months after treatment. Fourteen patients completed the study.

Results: Systolic and diastolic blood pressure values were similar in all patients at T3 and T6 compared to T0. However, during the study antihypertensive treatment was optimized (increased dose and/or addition of drugs) in 57% of patients ($n = 8$). No differences were observed in retinal arteriole structural parameters and in large artery stiffness. Basal capillary density was reduced by antiangiogenic drugs after 3 or 6 months.

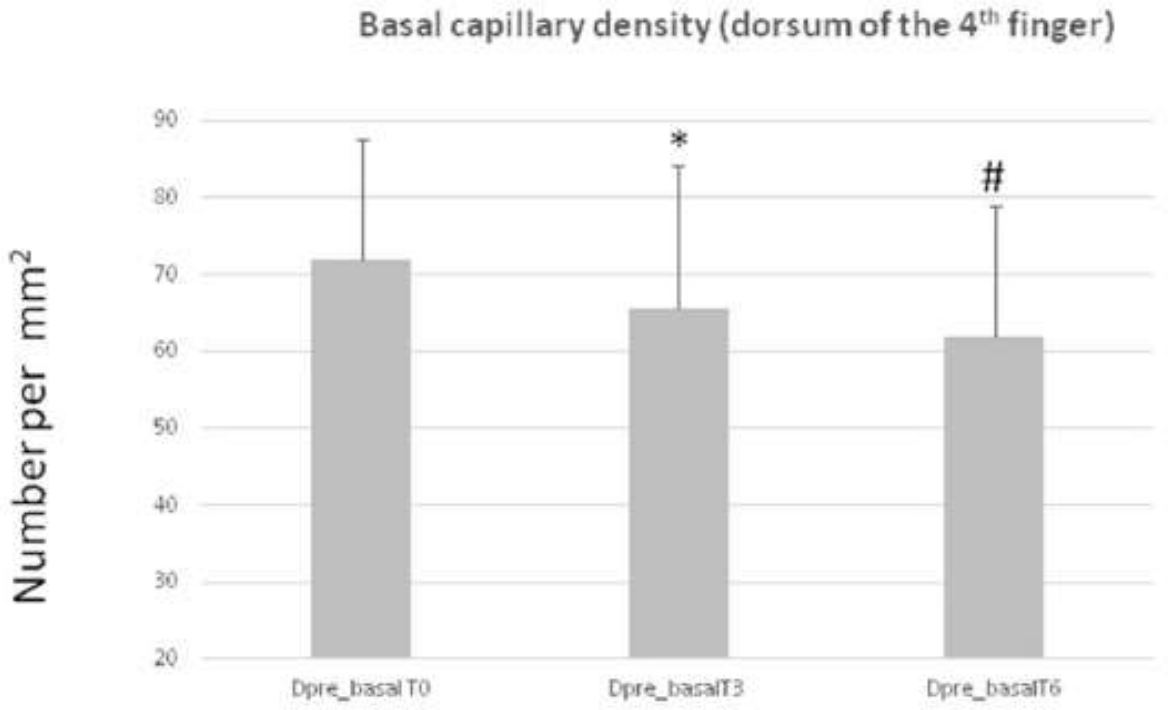

FIGURE 2 | Basal capillary density in the dorsum of the 4th finger (Dpre_basal) at the different time points (T0, T3, T6). *T3 vs. T0 $p = 0.03$; #T6 vs. T0 $p = 0.02$. Data are expressed as mean + standard deviation.

Wall cross sectional area ($\mu m^{2)}$	4,039.6 ± 1,491	3,943.5 ± 1,093.0	3,968.3 ± 1,026
Wall to lumen ratio (WLR)	0.30 ± 0.03	0.28 ± 0.02	0.28 ± 0.03
Capillaries			
Basal capillary density (dorsum), number per area unit	72.0 ± 15.8	65.5 ±18.6*	61.9 ± 17.1#
Total capillary density (dorsum), number per area unit	73.8 ± 14	69.6 ± 20.7	68.5 ± 11.9
Basal capillary density (forearm), number per area unit	56.6± 17.1	47.7 ± 13.2§	49.3 ± 11.6
Total capillary density (forearm), number per area unit	58.4 ± 16.2	54.5 ± 15.8	53.0 ± 8.0

*T-student analysis: *T3 vs. T0 p = 0.03; #T6 vs. T0 p = 0.02; §T3 vs. T0 p = 0.04.*
One-way ANOVA: dorsum basal capillary density p = 0.027, forearm basal capillary density p = 0.17.

Coschignano ME et al, Front Cardiovasc Med. 2021 Mar 10;8:651594. doi: 10.3389/fcvm.2021.651594. eCollection 2021.

Il progetto prevedeva i seguenti obiettivi:
1) Di validare l'apparecchiatura RTX-1 (Imagine Eyes) vs. il gold standard (biopsie tessutali + micromiografia).
2) Di valutare la riproducibilità e il valore clinico della misurazione del rapporto parete/lume delle arteriole retiniche (W/L).
3) Di valutare il possibile effetto di farmaci anti-angiogenetici, ampiamente utilizzati in oncologia, quali i modulatori del VEGF e gli inibitori di tirosina kinasi su indici di struttura del microcircolo valutati non invasivamente (W/L. densità capillare misurata mediante videomicroscopia) e su indici di distensibilità arteriosa.

Results and conclusion: Our data suggest that adaptive optics has a substantial advantage over SLDF in terms of evaluation of microvascular morphology, as WLR measured with adaptive optics is more closely correlated with the M/L of subcutaneous small arteries (r^2¼0.84, $P<0.001$ vs. r^2¼0.52, $P<0.05$, slopes of the relations: $P<0.01$ adaptive optics vs. SLDF). In addition, the reproducibility of the evaluation of the WLR with adaptive optics is far better, as compared with SLDF, as intraobserver and interobserver variation coefficients are clearly smaller. This may be important in terms of clinical evaluation of microvascular morphology in a clinical setting, as micromyography has substantial limitations in its clinical application due to the local invasiveness of the procedure.
De Ciuceis C et al, J Hypertens 2018; 36:1154-1163.

Conclusions: Our data suggest that an increase of antihypertensive treatment is necessary in patients treated with a TKI or a direct VEGF inhibitor, confirming pro-hypertensive effects of these drugs. However, under adequate blood pressure
control, microvascular structure seem to be partially preserved, since a worsening of basal capillary density but no changes in retinal arteriole morphology were observed.
Coschignano ME et al, Front Cardiovasc Med. 2021 Mar 10;8:651594. doi: 10.3389/fcvm.2021.651594. eCollection 2021.
